

State-Level Protections for LGBT+ Individuals and Hiring Discrimination on Non-Binary, Transgender Individuals: A Resume Audit Study

By: Maximilien Bielsa

August 31, 2026

maximilienbielsa.com

Abstract

Resume Audit Studies (RAS) are one of the only ways to document the existence of discrimination within hiring practices through callback rates. In this paper, I attempt to run a RAS to look into the use of pronouns on resumes. I investigate whether including pronouns on your resume will decrease the rate by which an employer requests more information, and whether the state and current LGBT+ laws protect these individuals. I find that pronouns are not as substantial an issue as the perceived gender of your name. I additionally find that Artificial Intelligence may impede any future RAS.

1 Introduction

Discrimination against LGBT+ individuals in the workplace has been a longstanding issue, predating the implementation of laws restricting the acknowledgment of these individuals in schools, as observed in states such as Florida. Consequently, there is a growing need for research on the discrimination faced by LGBT+ individuals and potential identifiers associated with them. This paper aims to explore one such identifier – the use of pronouns. While pronoun usage does not definitively indicate an individual’s position under the Trans-Umbrella,¹ it could serve as a tool for employers attempting to discriminate against them. This potential discrimination based solely on the presence of pronouns raises questions about the efficacy of state-level protections and the impact of political bias against workplace discrimination based on gender or sexuality. Previous economic papers have shown that using identifiers of queerness has resulted in discrimination (Mishel, 2016; Tilcsik, 2011).

The primary research questions guiding this investigation revolve around the impact of pronoun existence and content in gender-neutral job applications. Specifically, the study aims to evaluate the effectiveness of state-level LGBT+ protections in safeguarding individuals from discrimination in the workplace. Additionally, the paper seeks to show additional evidence into the inclusion of pronouns on the likelihood of receiving an interview compared to cases where pronouns are omitted for individuals who are recent college graduates. Finally, the type of pronouns used will also be tested to see if rates are different between themselves.

To address these questions, a Resume Audit Study (RAS) is employed. In a RAS, two nearly identical resumes are submitted to a job listing, differing only in one key aspect, allowing for the isolated examination of the effect of that particular difference on the likelihood of receiving a callback. This method ensures that individual and resume-specific characteristics remain as constant as possible, enabling a focused analysis of the impact of pronoun inclusion. A recent paper looked into the impact of pronouns on resumes, and

¹The Trans-Umbrella is a term referring to all individuals with a gender identity which is different from their assigned gender at birth. This includes transgender individuals, along with individuals who identify with identities such as gender-queer, gender-fluid, and non-binary.

found that non-binary pronoun usage led to discrimination (Eames, 2024a). Their research did not address state level and legal protections for these individuals, which is what I aim to investigate.

This paper's objectives can be categorized into one primary and three secondary focuses. The primary objective examined whether state-level employment protections for LGBT individuals extended to implied protections for these individuals based on pronoun use. The first secondary objective is to provide additional evidence to whether resumes with pronouns exhibit different callback rates compared to those without pronouns for the specific population of recent college graduates. The next secondary objective investigated if resumes with They/Them pronouns receive different callback rates compared to resumes using other pronouns, as this is a direct indicator of an individual being a transgender, compared to the other pronouns which could be an implied indicator. Finally I examined whether the 2024 election had a significant effect on the decisions these businesses made as whether to respond to these individuals.

The primary category of this experiment delves into the nuanced examination of selected states—North Carolina, Utah, Georgia, and New York. Each of these states serves a distinct purpose in shedding light on varied aspects of the overarching research questions. North Carolina, being a "Red" state without explicit protections for LGBT+ individuals in the workplace, offers insight into whether the absence of legal safeguards affects the hiring decisions of those who include pronouns on their resumes. Utah, also a "Red" state but with some workplace protections for the LGBT+ community, allowing me to explore whether these partial protections influence the hiring of individuals using pronouns. In contrast, Georgia, a "Blue" state lacking LGBT+ workplace protections, provides a scenario where political inclinations are more liberal, but legal safeguards are absent. Lastly, New York, a "Blue" state with robust workplace protections for LGBT+ individuals, allows us to investigate whether legal safeguards have a tangible impact on hiring practices. The differentiation among these states aims to disentangle the effects stemming from political climates and

the efficacy of existing legal protections. Additionally, the district in which these jobs were located was also tested, as these states do not have entirely “Blue” or “Red” populations.

Secondarily, this analysis focuses on the specific pronoun sets used in the research, aiming to provide a detailed understanding of their implications. My analysis incorporates the three most commonly known pronoun sets—He/Him, She/Her, and They/Them. By aligning the individual’s preferred name on the resume with the chosen pronouns, the study enhances the identification process for potential pronoun categories. This methodology ensures that the resonance between the pronoun and the name is an authentic representation of individuals in real life. For instance, an individual using He/Him pronouns is more likely to have a resume featuring a masculine or androgynous-sounding name, reflective of both their professional identity and real-life persona. Similarly, someone with She/Her pronouns would align with a feminine or androgynous name. The unique aspect arises with They/Them pronouns, as individuals employing this pronoun set may possess names spanning categories of masculine, feminine, and androgynous. This categorization results in seven distinct pronoun categories: She/Her with a feminine name, She/Her with an androgynous name, He/Him with a masculine name, He/Him with an androgynous name, They/Them with a feminine name, They/Them with a masculine name, and They/Them with an androgynous name. The random selection of pronoun categories from these seven ensures a thorough investigation into how the presence of pronouns affects callback rates in gender-neutral job applications.

For the third and final section of this analysis, the focus shifts to a more granular examination of the results obtained from the previous two sections. This section aims to discern any disparities in callback rates between resumes featuring They/Them pronouns and those with gender-implied pronouns (He/Him and She/Her). The investigation goes a step further by introducing a second layer of analysis to ascertain how variations in political landscapes and the presence or absence of LGBT+ protections impact the callback rates for these specific pronoun groups. By delving deeper into these nuanced comparisons, the study seeks to uncover subtle intricacies that may have been overlooked in broader assessments.

The results of the study examines how political affiliations in various states impact these outcomes, with the goal of informing potential policy recommendations based on the findings. I aim to provide insights into whether existing LGBT+ protections effectively shield individuals in gender-neutral job sectors or those openly expressing their pronouns on resumes. Overall, this endeavor aims to recognize and mitigate the disparities in hiring processes, encompassing social, political, and economic dimensions, particularly for transgender individuals and those who include pronouns on their resumes.

2 Past Resume Audit Studies

Resume audit studies have been a popular method to look into the discrimination that occurs from an employer reading a resume since “Are Emily and Greg More Employable than Lakisha and Jamal? A Field Experiment on Labor Market Discrimination”(Bertrand and Mullainathan, 2004) was published. Using a four-resume strategy with two high and two low-level resumes and two “black” and two “white” resumes, they found that resumes with “black” names received fewer callbacks from applications than applications with “white” names, and this gap was more substantial with perceived higher level resumes.

Since then, a number of papers have first tried to address gaps in our understanding of discrimination not based on race, sex, or sexual orientation which are relevant to the methodology and construction of this paper. These include; “The Value of Post-secondary Credentials in the Labor Market: An Experimental Study”(Deming et al., 2016), “College major, internship experience, and employment opportunities: Estimates from a résumé audit”(Nunley et al., 2016), and “Determinants of Callbacks to Job Applications: An Audit Study”(Farber et al., 2016), all of which show case RASs that impacted college-centric resume items. There is then a paper, “Experimental Research on Labor Market Discrimination”(Neumark, 2018), that summarizes a lot of the history of past RASs and how their results have changed overtime.

Several papers over time have looked into the specific effects on LGBT+ people through

resumes. This includes, “Sexual Orientation Discrimination in Hiring” (Weichselbaumer, 2003), which compared masculine and feminine women to their lesbian counterparts in Austria. Additionally, “Antecedents and Potential Moderators of the Relationship Between Attitudes and Hiring Discrimination on the Basis of Sexual Orientation” (Horvath and Ryan, 2003) took a different approach by instead asking individuals to rate a large number of resumes of gay and lesbian applicants. After this, “Pride and Prejudice: Employment Discrimination against Openly Gay Men in the United States” (Tilcsik, 2011) examined openly gay men in the US through a RAS by listing work at a gay organization on one resume and find that discrimination occurred in some states that were based on whether anti-discrimination laws existed and the attitudes of the area. A more recent paper, “Discrimination against Queer Women in the U.S. Workforce: A Résumé Audit Study” (Mishel, 2016) looked into the more broad group of queer women who could not be identified as a specific members of the LGBT+ community. This was done in a similar vein using four states to see if discrimination differed based on LGBT+ protections. They found that significant discrimination occurred and that discrimination did not seem to differ based on the protections in place for these individuals.

Two additional recent papers have been published in the last few years that are very close in vein to this paper. The first is one of the only resume audit studies which attempted to look into the discrimination against transgender people and was titled “Hiring Discrimination Against Transgender People: Evidence from a Field Experiment” (Granberg et al., 2020). This study was conducted in Sweden with low-skill jobs, where more information is required to apply to a job. In this vein, they used documents that indicated a name change from a name that indicated a switch from male to female or from female to male, whereas the other resume indicated a name change that took the place of similarly gendered names. This takes advantage of the fact that first name changes in Sweden are widespread, so employers are much less likely to act upon the fact that the individual underwent a name change. Even though they found that the rate of callbacks was lower for transgender in-

dividuals, they were unable to prove these results statistically. The following major paper, “Systemic Discrimination Among Large U.S. Employers” (Kline et al., 2022), is the first to use and test any form of pronouns on resumes. Doing a massive audit study using over 83,000 applications, they applied to the top 108 largest U.S. employers, where they sent four pairs of resumes to each opening with 500 unique names. Resumes differed on a large number of random differences, including race (black vs. white), gender of the name, the existence of gender-neutral they/them pronouns, the existence of an LGBTQ+ organization, and an implied age between 22 and 58. My research aims to directly focus on the efficacy of protections for LGBTQ+ individuals in the locations in which they applied. These protections could influence results, as states with protections could show greatly different results from states without protections.

3 Method

3.1 The Jobs, Resumes, Name Choice, and Pronouns

The primary objective of this paper is to address the following questions: How does the presence and content of an individual’s pronouns in gender-neutral job applications impact the likelihood of a company requesting an interview compared to those who omit pronouns? Additionally, do state-level LGBTQ+ protections effectively shield individuals from discrimination in the hiring process? Lastly, did the results of the 2024 election lead to additional levels of discrimination? To address these questions and align the study with real-world applicability, specific steps are outlined.

To begin, a definition of a "callback" is established, akin to prior literature. In this context, a callback is defined as either an email or a voicemail left for an applicant, soliciting a phone interview, an in-person interview, or additional information. Callback responses are coded as 1, while instances with no contact method or a denial are coded as 0.

Denials are also explicitly recorded. Similar to a callback, a separate variable was created for whether a company directly reached out to deny the application outright. In this case,

denials were recorded as 1, and a callback or no contact was recorded as 0.

The resumes are meticulously crafted to resemble those of recent undergraduate degree graduates, as this demographic is more likely to regularly use pronouns when introducing themselves. The choice of the undergraduate degree location is based on U.S. News 2022-2023 rankings (U.S. News and World Report, 2022), focusing on the top two state colleges within each state, with rankings primarily falling between 35 and 105. The selection includes Utah State University, though it deviates from this range. Work experience on both resumes is standardized to include roles as a secretary or treasurer for a liberal club on campus, aligning with literature recommendations to mitigate bias associated with political affiliations.

Selected job categories exhibit gender-neutral workforce ratios based on census data (33.4%-66.6% women) (United States Department of Labor, 2024). Since the census only collects sex based on the binary options of male and female, this is the optimum category for equal treatment across the different pronoun categories. Job categories also align with industries that typically require, at most, an undergraduate degree. The majority of applicants are tailored to the job position, maintaining realism. One example of this would be an application for a marketing and sales job paired with a marketing degree from the assigned university. More information about the universities and majors used can be located in the appendix.

Care is taken to avoid unreasonable pairs of names that may signal perceived gender. Names are classified as masculine, feminine, or androgynous in this context. While we are interested in pronouns in conjunction with the individual's names, we want to be careful not to make unreasonable pairs. For example, most transgender people put their preferred name on their resume as a way to avoid outing themselves. This means that someone who identifies as a transgender male is very unlikely to have a non-masculine name on their resume. This is different for individuals with non-binary pronouns. Since the non-binary umbrella involves persons who may be willing to keep their names given at birth, have a constantly changing gender identity and use multiple differently gendered names (such as genderfluid), or may

have changed their name to a more androgynous name, we cannot restrict these pronouns. We also want to make sure racial bias does not play a part in this, so we want to use “white” sounding names. The proposed first names are listed below:

Proposed First Names	Masculine	Androgynous	Feminine
He/Him	Michael, Matthew, Nicholas, and Joseph	Casey, Riley, Jordan, and Devon	X
They/Them	Michael, Matthew, Nicholas, and Joseph	Casey, Riley, Jordan, and Devon	Emily, Sarah, Julia, and Samantha
She/Her	X	Casey, Riley, Jordan, and Devon	Emily, Sarah, Julia, and Samantha

First names are sourced from birth certificate data (Social Security Administration, 2024) from the target range of individuals born approximately in 2001 to target individuals going straight to undergrad after high school and staying there for between 3 and 6 years. Proposed last names, such as Miller, Baker, Murphy, and Cook, are chosen based on commonality, ensuring over 80% association with individuals of white ethnicity.

Emails were created based on the names of the individuals developed, adding two random numbers after their names. A total of 48 emails were created to match the different name combinations. They were then linked using the job that was applied to for that response of whether they were the pronounced or non-pronounced resume. Meanwhile, a total of 24 phone numbers/voice mails were created for the four states that will be used with area codes near their school’s location.

The collection of the data for this study was conducted over two years and two time periods. The first time period was from March 2024 until October 2024. This first time period is slightly shortened due to the 2024 national election, which I felt may influence that year’s results. From this, I developed the third research question above to see if the election

influenced the labor markets. As a way to contrast with the first year’s results, the rest of the study was conducted in a second time period. The second time period was from March 2025 until December 2025.

3.2 Randomization, Websites, and States Selected

Two fictional resumes are created to apply to a single job listing sourced from platforms such as Indeed, Glassdoor, Craigslist, and ZipRecruiter. Image exclusion is maintained to avoid gender suggestions, and jobs requiring images are excluded. Pronouns are left blank when prompted, allowing for the examination of the impact of listed pronouns on the resume and avoiding potential biases at an early application stage. An example would be if a manager were to sort the resume based on the individual’s pronouns alone, possibly making the early assumption that someone using pronouns is left-leaning. Along with this, any websites that require pronouns for both individuals would not be used either, as this would defeat much of the purpose of this analysis if both individuals’ pronouns were known.

Applications will be restricted to jobs that do not require you to leave the site of the application and prioritize “Easy Apply” or “Quick Apply” functions, in line with other RASs. Jobs with titles of confidential (meaning the hiring company is secret) and whether a hiring firm, rather than a specific job, is being applied to will also be specified.

The applications will be sent to four specific states. These states include New York, Georgia, Utah, and North Carolina. These states were chosen for specific reasons relating to LGBT+ laws and political bias, primarily based on the most recent 2022 Senate races and 2024 presidential election, as these are state-wide elections. In this context, New York and North Carolina are considered Blue states that elected a Democratic senator, while Utah and Texas are both Red states that elected a Republican senator. Along these lines, New York and Utah have legal protections for LGBT+ individuals (Utah being the only Red state that does). In contrast, North Carolina and Georgia do not have explicit legal protections

protecting LGBT+ individuals (Movement Advancement Project., 2024). This method is imperfect, as many consider North Carolina and Georgia more “Purple” states that swing back and forth.

Another issue is that most job applications posted online in locations for job sites will be in major cities, which tend to lean more democratic. This paper hopes that implanting the results of the presidential and house of representatives races by area will remove this confounding variable. To attempt to look more in-depth towards whether the city matters, the 2024 House of Representatives election results for that city’s candidate/district will also be recorded based on the company’s listed address. Should the company not list its full address, the results of all elections in that city will be averaged into a category of Republican and Democratic vote share. Based on the census definition of urban, any city with over 50,000 people will be considered urban.

To combat the Heckman-Siegelman critique², I also added other variations that are consistent through resume pairs sent to one job, but are random across jobs. As a result resume pairs included randomization of: the years of undergrad (3-6 years), knowledge of Spanish (proficient or not), retail manager experience (1-2 years), and time being a tutor at the university (1-3 years).

With all of this information, I then created 1600 randomized resume-pairs with different weights for each category specified above. Most categories were given equal weights among the different options. The two exceptions to this were job type and website. Jobs were given weights for randomization based on Department of Labor statistics for how many individuals were working these jobs in the US (United States Department of Labor, 2024). Additionally, website’s were given different weights based on the market share of the sites themselves according to (6sense, 2024).

²Heckman-Seigelman critique, is a critique which solved in (Neumark, 2018) requiring variability in the quality across both resumes to reduce possible errors in correlated variances.

3.3 Cases Dropped

Several jobs were also dropped due to the existence of spam offers. Some jobs, after application, will send an email quickly asking for credit card information or having a suspicious link. Outlook can identify these and will mark them as spam. This also occurred for few jobs, and was mostly related to Craigslist postings. These observations had to be dropped as a result. What occurred much more frequently, was that jobs were deleted before time is available to send the second application. These observations were also dropped.

The total number of applications sent was 2,067. After these adjustments were made I was left with 1,844 applications for 922 jobs. This represents that about 10% of jobs.

4 Models

This empirical strategy is employed to answer the questions sought out to be answered in this paper. Beginning with equation 1, I attempt to examine whether there is a difference in the outcomes for having pronouns on a resume. In all equations, Z can be used as either callbacks or denials.

$$Z = \alpha + \beta X_i + \delta_1 C_i + \delta_2 F_j + \varepsilon_{ij} \quad (1)$$

Here, α is the intercept, and β is the variable of interest. X_i is a binary variable, which is 1 if a resume has pronouns, and 0 if it does not. C_i represents a vector of resume characteristics and F_j represents a vector of firm characteristics obtained from the job posting. After this a number of Equations 2 and 3 below were created to answer the other questions of interest.

$$Z = \alpha + \beta_1 X_i + \beta_2 S_j + \beta_3 [S_j * X_i] + \delta_1 C_i + \delta_2 F_j + \varepsilon_{ij} \quad (2)$$

$$Z = \alpha + \beta_1 X_i + \beta_2 P_j + \beta_3 [P_j * X_i] + \delta_1 C_i + \delta_2 F_j + \varepsilon_{ij} \quad (3)$$

Equation 2 looks into whether there is a significance based on which state the appli-

cation was sent. We do this by making S_j which is a set of vectors for three of the states used in this analysis. Equation 3 is used to estimate whether states with protections for LGBT+ individuals differed from states without those protections. In this model, P_j is a vector for whether the job's state had protections for employment for LGBT+ individuals. Additionally, Equations 2 and 3 were run with and without interaction terms, and Equations 1-3 were also run with only the resume pairs for each pronoun set to see if different pronoun sets held different results.

I finally edit the first equation, into Equation 6.

$$Z = \alpha + \beta N_i + \delta_1 C_i + \delta_2 F_j + \varepsilon_{ij} \quad (4)$$

$$Z = \alpha + \beta_1 X_i + \beta_2 R_j + \beta_3 [R_j * X_i] + \delta_1 C_i + \delta_2 F_j + \varepsilon_{ij} \quad (5)$$

$$Z = \alpha + \beta_1 X_i + \beta_2 D_j + \beta_3 [D_j * X_i] + \delta_1 C_i + \delta_2 F_j + \varepsilon_{ij} \quad (6)$$

In this result, I remove all resumes without pronouns. Here I test B_i which is 1 if the resume uses They/Them pronouns and 0 if it uses He/Him or She/Her pronouns. This is to test whether non-binary pronouns show a statistical difference from binary pronounced resumes. Equations 4 and 5 look into the political alignment of the congressional districts these jobs are in and whether this had an impact when comparing resumes with pronouns to each other. For these equations R_j is the percentage of vote share the republican got in the 2024 house of representatives election while D_j is the vote share for the democratic candidate. Lastly, equations 1-6 were run with and without resume and firm characteristics.

5 IRB Approval and Power Testing

After receiving IRB approval in the summer of 2023, a preliminary power test was executed in fall 2023 in New Jersey, encompassing 150 or more job listings and over 300 resumes.

The primary aim of this test was to investigate potential discriminatory patterns and establish a baseline for discrimination, providing essential insights to inform the subsequent full-scale study. New Jersey was deliberately chosen for this initial examination due to its classification as a "Blue" state with established LGBT+ protections. The rationale behind this choice lies in the expectation that, in a state with comprehensive protections, any observed discrimination would likely represent the minimum baseline. This strategic selection allows for a comparative analysis, anticipating that other states might exhibit equal or more significant impacts, aiding in determining an appropriate sample size for the comprehensive study.

Outlined below are the outcomes derived from the power test, employing both Probit and Logit models, and incorporating all previously specified control measures. This measure only took into account Equation 2a, as that was initially the primary area of interest.

Table 1: Results For Basic Marginal Models For Power Test

	Logistic
	Interview
Pronounced	-0.0290
	(0.0277)
N	278

Standard errors in parentheses

* $p < .10$, ** $p < .05$, *** $p < .01$

Model uses a marginal logistic model of Equation 1 to show the impact of a resume having pronouns on an interview occurring being between a 2.9% and 3.24% difference. This Model uses/reports marginal effect values.

Through the test, the basic results in New Jersey showed that there was between a 2.9 and 3.2 percent decrease in callback rate if you had pronouns on your resume. Utilizing the computations outlined in the paper titled "So you want to run an experiment, now what? Some simple rules of thumb for optimal experimental design" (List et al., 2011) and conservative expectations of the differences in states with protections compared to those without protections from previous papers (Tilcsik, 2011) and (Mishel, 2016), it was determined that the optimal sample size should be about 1400. Considering the additional factor that ap-

proximately 13% of job opportunities closed after one application, or were labeled as spam by our email filter, the optimal sample size has been chosen to be 1600 jobs split as evenly as possible across the four states.

6 Full Test Results

The results of the full study are below. Unfortunately, there are major problems which have caused this paper to be under powered. Due to a degradation of the job market, the numbers of jobs that were believed to be available when the power test was conducted in mid 2023 was different, and the size was harder to attain for the chosen job categories.

Figure 1: Diminishing of Job Postings on Indeed

Job postings on Indeed have hit points equivalent to the Coronavirus Recession.(Federal Reserve Bank of St. Louis, 2026)

6.1 Likelihood of AI presence in testing

Additionally, some issues with this paper seem to be the possibility of interaction with Artificial Intelligence, which is much more frequently being employed to scan resumes before humans. This is despite, when asked and applying on websites, I specifically asked to not be

reviewed by AI when prompted. Using the chart of time until a response is received, I find a stark peak at three days after the resume is sent out. This peak is substantial in denials, and does not show up in approvals. This is consistent across years, and shows that many resumes were likely run through an initial program to evaluate whether they should be seen by an actual human.

Figure 2: Days until a response for Denials(left) and Callbacks(right)

This likely caused substantial problems in this research, as AI may value pronouns on a resume differently than humans, or they may be indifferent to the salience of the pronouns themselves. It could also stand to reason that if AI were to more highly value masculine individuals, it could cause He/Him pronouns to be a positive, where individuals might assume political bias. This could easily cause an inability to reject a null hypothesis, without work to disentangle the effects.

6.2 Summary Statistics

Below are the full sample summary statistics in Table 2. Additionally, all used Variables are broken down into Outcome variables of interest, and whether it was used as either a

control for the job or whether it was used as a control on the submitted resume. Additionally, Tables 11-13 have a breakdown of the summary statistics by each pronoun group. The three pronoun groups are not substantially different other than He/Him pronoun resumes do not have any feminine names, and She/Her pronoun resumes do not have any Masculine names, which makes both of those underestimated in the full summary statistics.

Table 2: Full Sample Summary Statistics

		(1) Full Sample			
	count	mean	sd	min	max
Outcome Variables					
Callback	1844	.0276573	.1640333	0	1

N	1844				

6.3 Regression Results

Results for the primary equations will be talked about here; more detailed testing and robustness tests for all the models will be located in the appendix. If any models were missing, this was because the amount of data for callbacks of that pronoun type were not enough to run the logistic regression for that question. This mostly occurred with She/Her pronouns as their callback rate was the lowest and they also happened to end up with the lowest sample size.

Table 3 shows the results of Equation 1 when the dependent variable is whether the resume received a Callback.

Table 3: The Baseline Impact of Pronouns being on a Resume				
	(1) Callback	(2) Callback	(3) Callback	(4) Callback
Baseline				
Pronouns	0.121 (0.284)	0.122 (0.285)	0.340 (0.323)	0.329 (0.325)
Obvious Pronouns			-0.506 (0.405)	-0.482 (0.408)
Job Specific		X		X
Resume Specific			X	X
<i>N</i>	1844	1794	1844	1794
<i>t</i> statistics in parentheses				
* $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$				

Model uses equation 1. Job and Resume Specific Controls are located in Table 2. This Model reports values of Log-Odds Ratios and Standard Errors.

The results of this test shows that, while resume specific attributes have a large effect on the results, job-specific attributes do not. The direction of magnitude is much less intuitive, as it seems that the presence of pronouns led to an increase in callbacks. There is also no statistical significance, but it is worth noting that the more obvious the pronouns are, the less likely the resumes were to receive a callback.

Table 4 also uses Model 1, except the dependent variable is whether the resume received an explicit denial.

Table 4: The Baseline Impact of Pronouns being on a Resume

	(1)	(2)	(3)	(4)
	Denials	Denials	Denials	Denials
Baseline

Model uses equation 1. Job and Resume Specific Controls are located in Table 2. This Model reports values of Log-Odds Ratios and Standard Errors.

Table 4 shows similar results to Table 3, except it has higher levels of significance, likely because more denials were received in this study. Here I essentially see the opposite effect from Table 3, where the existence of pronouns decreases the rate of denials. However, in the case where the pronouns are more obvious, resumes are similarly more likely to cause denials.

I then analyzed Equation 1 by splitting the results by pronoun grouping. In Table 5, I report the estimates with controls, but in the Appendix I list those results in three individual batches: one with no controls, one with only job controls, and one with only resume controls.

Table 5: Baseline Results by Pronoun Group With All Controls

	He/Him Denial	She/Her Denial	They/Them Denial	He/Him Callback	They/Them Callback
With All Controls					
Pronouns	-0.569 (0.374)	-0.133 (0.379)	-0.201 (0.329)	0.643 (0.577)	0.0748 (0.529)
Masculine	-0.403 (0.300)		0.0596 (0.340)	0.280 (0.594)	0.165 (0.627)

t statistics in parentheses

* $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$

Model uses equation 1. Job and Resume Specific Controls are located in Table 2. This Model uses all controls, and is split by independent variable, and by pronoun. This Model reports values of Log-Odds Ratios and Standard Errors.

From these results, I see that the main impact comes from those with He/Him pronouns. In this case it seems that despite these being non-binary jobs, they seem to have a preference for more masculine named and pronounced individuals, leading to these individuals being more likely to be called back, and less likely to be denied. Meanwhile, the more obvious the pronouns, the more of a negative impact was experienced.

Below I present Table 6, which attempts to answer whether the state has a significant impact on the level of callbacks and denials.

Table 6: State Results by Pronoun Group With All Controls

	He/Him Denial	She/Her Denial	They/Them Denial	He/Him Callback	They/Them Callback
All Controls					
Pronouns	-0.590 (0.375)	-0.157 (0.385)	-0.187 (0.335)	0.951 (0.659)	0.0568 (0.532)
Georgia	0.0955 (0.393)	0.645 (0.536)	1.144* (0.463)	3.397* (1.653)	-0.380 (0.650)
Utah	-0.299 (0.418)	1.290** (0.514)	1.397*** (0.466)	4.783*** (1.622)	0.459 (0.574)
New York	-0.245 (0.439)	0.129 (0.613)	0.424 (0.514)	2.927* (1.690)	-1.194 (0.850)

<i>N</i>	546	530	760	340	716

t statistics in parentheses

* $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$

Model uses equation 2. Job and Resume Specific Controls are located in Table 2. This Model uses all controls, and is split by independent variable, and by pronoun. This Model reports values of Log-Odds Ratios and Standard Errors.

These results show that Utah and Georgia were much more statistically likely to give callbacks to resume groups that were made for He/Him pronouns, but not if those pronouns were obvious. At the same time, they were both much more likely to send a quick denial to resume pairs where one contained They/Them pronouns. In Table 23 of the Appendix, I also interact the states with pronouns, and the effects are not significant for the interaction terms.

Table 7 then looks at whether LGBTQ+ protections cause higher rates of callbacks or denials.

Table 7: LGBTQ+ Protections Results by Pronoun Group With All Controls

	He/Him Denial	She/Her Denial	They/Them Denial	He/Him Callback	She/Her Callback	They/Them Callback
All Controls						
Pronouns	-0.589 (0.375)	-0.138 (0.380)	-0.195 (0.330)	0.779 (0.604)	0.537 (0.701)	0.0713 (0.530)
LGBTQ+ Protections	-0.321 (0.304)	0.474 (0.320)	0.260 (0.283)	1.583** (0.689)	-0.205 (0.639)	0.124 (0.447)
Masculine	-0.435 (0.302)		0.0400 (0.341)	0.434 (0.622)		0.169 (0.627)
Obvious Pronouns	0.355 (0.446)	0.501 (0.419)	-0.118 (0.406)	-2.361** (1.200)	-0.370 (0.812)	0.0540 (0.609)

t statistics in parentheses

* $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$

Model uses equation 3. Job and Resume Specific Controls are located in Table 2. This Model uses all controls, and is split by independent variable, and by pronoun. This Model reports values of Log-Odds Ratios and Standard Errors.

In this Table, the only level of significance is for He/Him pronouns, and this estimates that the more obvious the pronouns, the less likely that you are to be called back at the same time. This estimates some small amount of discrimination, as long as the pronouns are salient. In the appendix, this model is also run with interaction terms, and has a very similar result with less significance. In Table 30 of the Appendix, I also interact the LGBTQ+ protections with pronouns, and the effects are not significant for the interaction terms.

Next, Tables 8 and 9 look at whether non-binary pronouns had different levels of callbacks or denials in comparison to binary pronouns.

Table 8: Non-Binary Pronoun Denial Results With All Controls

	(1)	(2)	(3)	(4)
	Denial	Denial	Denial	Denial
Non-Binary Baseline				
Non-Binary Pronouns	-0.309 (0.244)	-0.308 (0.247)	-0.250 (0.250)	-0.245 (0.253)
Masculine			-0.399 (0.303)	-0.437 (0.305)
Obvious Pronouns			0.169 (0.236)	0.182 (0.237)
Feminine			-0.223 (0.285)	-0.263 (0.290)
Job Specific		X		X
Resume Specific			X	X
<i>N</i>	922	922	922	922

t statistics in parentheses

* $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$

Model uses equation 4. Job and Resume Specific Controls are located in Table 2. This Model reports values of Log-Odds Ratios and Standard Errors.

Table 9: Non-Binary Pronoun Callback Results With All Controls

	(1)	(2)	(3)	(4)
	Callback	Callback	Callback	Callback
Non-Binary Baseline				
Non-Binary Pronouns	0.136 (0.393)	0.111 (0.400)	0.0159 (0.407)	-0.0154 (0.414)
Masculine			0.176 (0.512)	0.190 (0.517)

Resume Specific			X	X
<i>N</i>	922	897	922	897

t statistics in parentheses

* $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$

Model uses equation 4. Job and Resume Specific Controls are located in Table 2. This Model reports values of Log-Odds Ratios and Standard Errors.

These results are not significant, but based on the near significance of the name being masculine and feminine, it seems that feminine names were less likely to be called back, while masculine names were more likely to not receive a denial.

Finally, we can look at the republican vote share within the congressional district that the job was located.

Table 10: Republican Vote Share's Impact by Pronoun Group With All Controls

	He/Him Denial	She/Her Denial	They/Them Denial	He/Him Callback	She/Her Callback	They/Them Callback
All Controls						
Republican Vote Share in Congressional District	-0.00822 (0.0127)	0.0326** (0.0145)	0.0102 (0.0114)	0.0173 (0.0268)	0.00587 (0.0231)	0.0193 (0.0183)
Masculine	-0.666 (0.482)		0.187 (0.516)	-0.279 (1.037)		0.529 (0.977)
Obvious Pronouns	0.441 (0.471)	0.510 (0.437)	-0.154 (0.418)	-3.347** (1.688)	-0.200 (0.826)	-0.163 (0.665)
Feminine		-0.690 (0.454)	0.100 (0.505)		-0.350 (0.863)	1.344 (0.871)
<i>N</i>	273	265	380	194	193	278

t statistics in parentheses

* $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$

Model uses equation 5. This Model is also restricted to the resumes that have pronouns on them. Job and Resume Specific Controls are located in Table 2. This Model uses all controls, and is split by independent variable, and by pronoun. This Model reports values of Log-Odds Ratios and Standard Errors.

From this we see the only level of significance is in She/Her pronounced resumes. We see that the higher the republican vote share in a congressional district, the more likely an individual with She/Her pronouns is to receive a denial.

7 Conclusion

Due to the low sample size, and the possibility of interference from Artificial Intelligence, reaching a conclusion based on statistical significance is not possible. However, three things do seem to be clear.

Firstly, despite these industries being gender neutral, there seems to be a bias towards masculine individuals and away from feminine individuals, which is more prevalent in republican leaning areas. This bias is present in both callbacks and denials across all models. Secondly, there is evidence that the more salient the pronoun is, the more likely discrimination is to occur, regardless of pronoun group. This leads to both fewer callbacks and more denials. Finally, AI is something that need to be more thoroughly examined in future resume audit studies. Researchers will need to plan and make a conscious effort to disentangle the discrimination from individuals and from AI itself.

<i>N</i>	546	530	760	546	514	734

t statistics in parentheses

* $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$

Model uses equation 3. Resume and Job Specific Controls are located in Table 2. This Model uses both Resume and Job Specific Controls, and is split by independent variable, and by pronoun. This model also includes interactive terms for the LGBTQ+ protections with the presence of pronouns. This Model reports values of Log-Odds Ratios and Standard Errors.

Table 31: Republican Vote Share's Impact by Pronoun Group No Controls

	He/Him Denial	She/Her Denial	They/Them Denial	He/Him Callback	She/Her Callback	They/Them Callback
No Controls						
Republican Vote Share in Congressional District	-0.00604 (0.0113)	0.0313** (0.0137)	0.00834 (0.0109)	-0.00315 (0.0192)	0.00681 (0.0216)	0.0135 (0.0169)
<i>N</i>	277	265	380	277	265	380

t statistics in parentheses

* $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$

Model uses equation 5. This is restricted down to the resumes that have pronouns on them. This Model uses No Controls, and is split by independent variable, and by pronoun. This Model reports values of Log-Odds Ratios and Standard Errors.

Table 32: Republican Vote Share's Impact by Pronoun Group Job Controls

	He/Him Denial	She/Her Denial	They/Them Denial	He/Him Callback	She/Her Callback	They/Them Callback
Job Controls						
Republican Vote Share in Congressional District	-0.00545 (0.0121)	0.0303** (0.0138)	0.00915 (0.0112)	-0.0101 (0.0213)	0.00815 (0.0217)	0.0148 (0.0172)
<i>N</i>	273	265	380	273	257	367

t statistics in parentheses

* $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$

Model uses equation 5. This Model is also restricted to the resumes that have pronouns on them. Job Specific Controls are located in Table 2. This Model uses Job Specific Controls, and is split by independent variable, and by pronoun. This Model reports values of Log-Odds Ratios and Standard Errors.

Table 33: Republican Vote Share's Impact by Pronoun Group Resume Controls

	He/Him Denial	She/Her Denial	They/Them Denial	He/Him Callback	She/Her Callback	They/Them Callback
Resume Controls						
Republican Vote Share in Congressional District	-0.00792 (0.0120)	0.0333** (0.0142)	0.0100 (0.0111)	0.00705 (0.0210)	0.00778 (0.0225)	0.0161 (0.0177)
Masculine	-0.600 (0.460)		0.118 (0.498)	0.185 (0.782)		0.478 (0.945)
Obvious Pronouns	0.307 (0.443)	0.446 (0.422)	-0.263 (0.405)	-2.079* (1.119)	-0.356 (0.786)	-0.249 (0.624)
Feminine		-0.661 (0.431)	0.173 (0.486)		-0.361 (0.828)	1.327 (0.832)
<i>N</i>	277	265	380	197	197	288

t statistics in parentheses

* $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$

Model uses equation 5. This Model is also restricted to the resumes that have pronouns on them. Resume Specific Controls are located in Table 2. This Model uses Resume Specific Controls, and is split by independent variable, and by pronoun. This Model reports values of Log-Odds Ratios and Standard Errors.

Table 34: Democratic Vote Share's Impact by Pronoun Group No Controls

	He/Him Denial	She/Her Denial	They/Them Denial	He/Him Callback	They/Them Callback
No Controls					
Democratic Vote Share in Congressional District	0.00669 (0.0104)	-0.0212** (0.0103)	-0.00796 (0.00954)	0.00548 (0.0175)	-0.0105 (0.0144)
<i>N</i>	277	265	380	277	380

t statistics in parentheses

* $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$

Model uses equation 6. This Model is also restricted to the resumes that have pronouns on them. This Model uses No Controls, and is split by independent variable, and by pronoun. This Model reports values of Log-Odds Ratios and Standard Errors.

Table 35: Democratic Vote Share's Impact by Pronoun Group Job Controls

	He/Him Denial	She/Her Denial	They/Them Denial	He/Him Callback	They/Them Callback
Job Controls					
Democratic Vote Share in Congressional District	0.00607 (0.0111)	-0.0202* (0.0104)	-0.00913 (0.00986)	0.0123 (0.0199)	-0.0120 (0.0146)
<i>N</i>	273	265	380	273	367

t statistics in parentheses

* $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$

Model uses equation 6. This Model is also restricted to the resumes that have pronouns on them. Job Specific Controls are located in Table 2. This Model uses Job Specific Controls, and is split by independent variable, and by pronoun. This Model reports values of Log-Odds Ratios and Standard Errors.

Table 36: Democratic Vote Share's Impact by Pronoun Group Resume Controls

	He/Him Denial	She/Her Denial	They/Them Denial	He/Him Callback	They/Them Callback
Resume Controls					
Democratic Vote Share in Congressional District	0.00880 (0.0111)	-0.0222** (0.0107)	-0.00878 (0.00963)	-0.00397 (0.0191)	-0.0144 (0.0156)
